Exception Handling in Haskell

Abstract

Implementing exception handling in Haskell. Unlike other libraries, use named exception handlers. Use the λ^{try}-calculus to formalize and explore a series of translations between multiple calculi to arrive at a translation into Haskell. Explore properties of this translation including soundness and completeness. Publish useable Haskell library.

Delimited-Continuation Calculus

Simon Peyton-Jones *et al.* extended the λ-calculus with additional operators in order create a framework for implementing delimited continuations [1]. This calculus will be referred to as the delimited-continuation calculus or DCC. Many calculi have been devised with control mechanisms. Like the $\lambda\mu$-calculus, these control mechanisms are all specific instances of delimited and undelimited continuations. DCC provides a set of operations that are capable of expressing many of these other common control mechanisms.

The grammar of DCC is an extension of the standard λ-calculus:

The additional terms behave as follows:

- *newPrompt* returns a new and distinct prompt.

- *pushPrompt*'s first argument is a prompt which is pushed onto the continuation stack before evaluating its second argument.

Definition 2.0.1 (GRAMMAR RULES FOR DCC)

(Variables) $x, y, \ldots$

(Expressions) $e \quad ::= \quad x \mid \lambda x.e \mid e\ e'$

$\qquad\qquad\qquad\qquad\ \ \mid \quad newPrompt \mid pushPrompt\ e\ e$

$\qquad\qquad\qquad\qquad\ \ \mid \quad withSubCont\ e\ e \mid pushSubCont\ e\ e$

- *withSubCont* captures the subcontinuation from the most recent occurrence of the first argument (a prompt) on the excution stack to the current point of execution. Aborts this continuation and applies the second argument (a λ-abstraction) to the captured continuation.

- *pushSubCont* pushes the current continuation and then its first argument (a subcontinuation) onto the continuation stack before evaluating its second argument.

Whereas the original grammar for the DCC abstract machine presents sequences as values, it has an implicit semantics that is unpacked in the implementation details. Here, we present sequences as expressions and define their semantics explicitly as:

Definition 3.0.2 (Semantics of a sequence of continuations)

Let D_i denote some term with a hole and $D_i[v]$ denote the term D_i with the hole filled by $v4$:

$$\langle (D_1 : D_2 : \cdots : D_n), D', E, q \rangle \quad \Rightarrow \quad \langle \lambda x.D_n[D_{n-1}[\ \ldots D_1[x] \ldots]], D', E, q \rangle$$
